

Giant planets near the 5:2 resonance and their influence on terrestrial planets in the habitable zone

E. Pilat-Lohinger (Univ. Vienna)

Aron Süli (Univ. Budapest)

Philippe Robutel (IMCCE)

Florian Freistetter (Univ. Jena)

Motivation

A study of
Extra-solar planetary systems
similar to
our solar system

Classification of the known multi-planet systems (S.Ferraz-Mello, 2005)

- **Class Ia** → Planets in mean motion resonance
- **Class Ib** → Low-eccentricity near-resonant planet pairs
- **Class II** → Non-resonant planets with significant secular dynamics
- **Class III** → Hierarchical planet pairs

Initial Conditions and Computations

Jupiter: on its orbit

Saturn: $a_{\text{sat}} = 8 \dots 11 \text{ AU}$

$m_{\text{sat}} = 1 \dots 30 m_{\text{Sat}}$

Testplanets in the HZ:

$a_{\text{tp}} = 0.6 \dots 1.6 \text{ AU}$

Mercury 6 (J. Chambers)

Integration time:

20 mio years

HZ: maximum ecc.

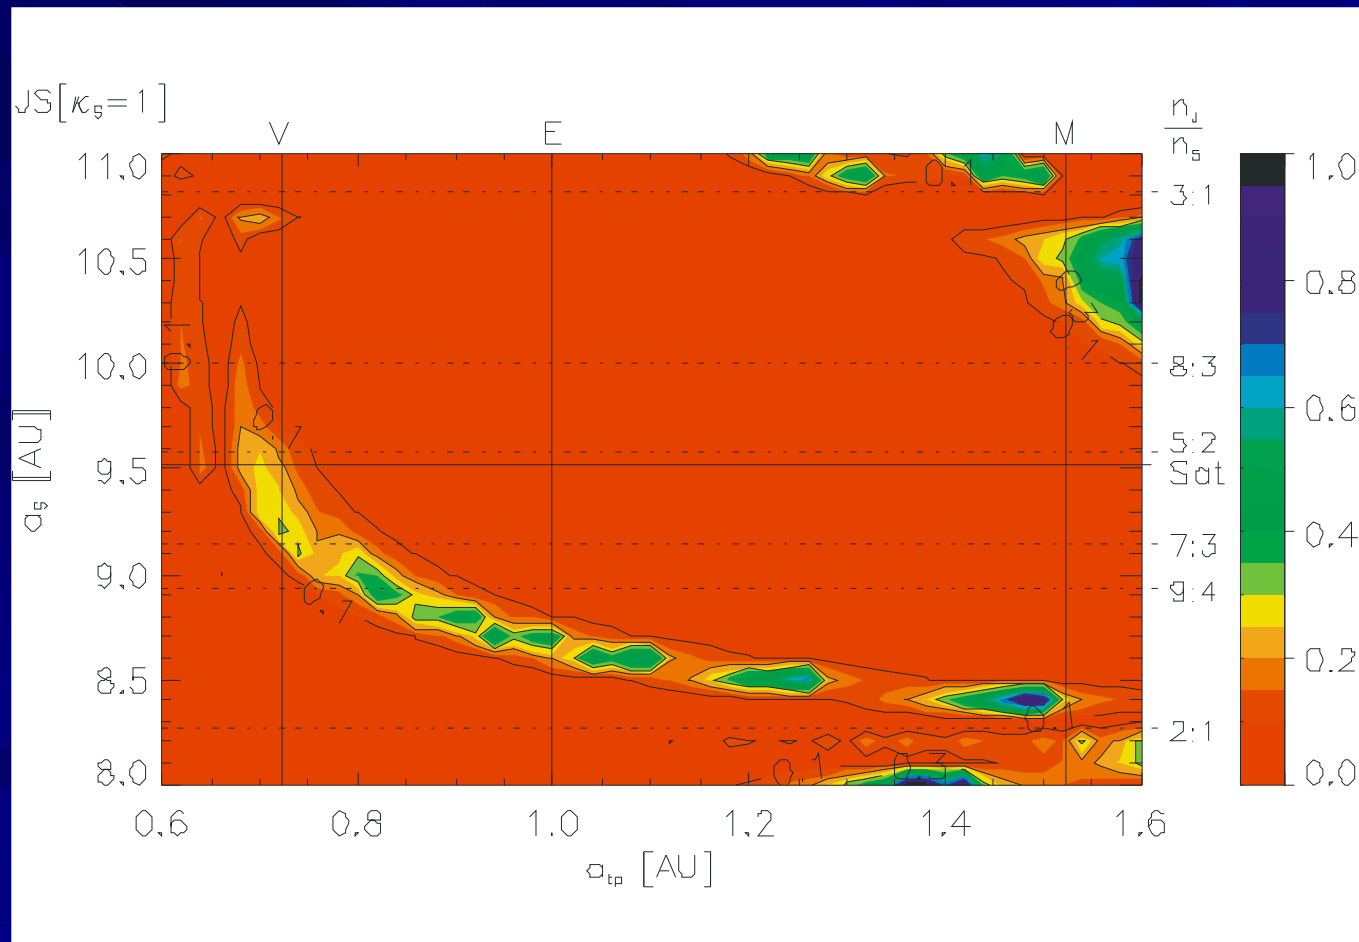

HZ im Sonnensystem:

- Kasting: 0.93 – 1.3 AU
- Mischna: 0.93 – 1.7 AU
- Forget: 0.93 – 2 AU

$a < 0.93 \text{ AU}$ → H₂O becomes a major atmospheric compound and is rapidly lost to space after UV photolysis

$a > 1.3 \text{ AU}$ → CO₂ condensates in the atmosphere producing CO₂-clouds, that can affect significantly the T-CO₂ coupling
